

---

## How to work on GET requests, with an example.

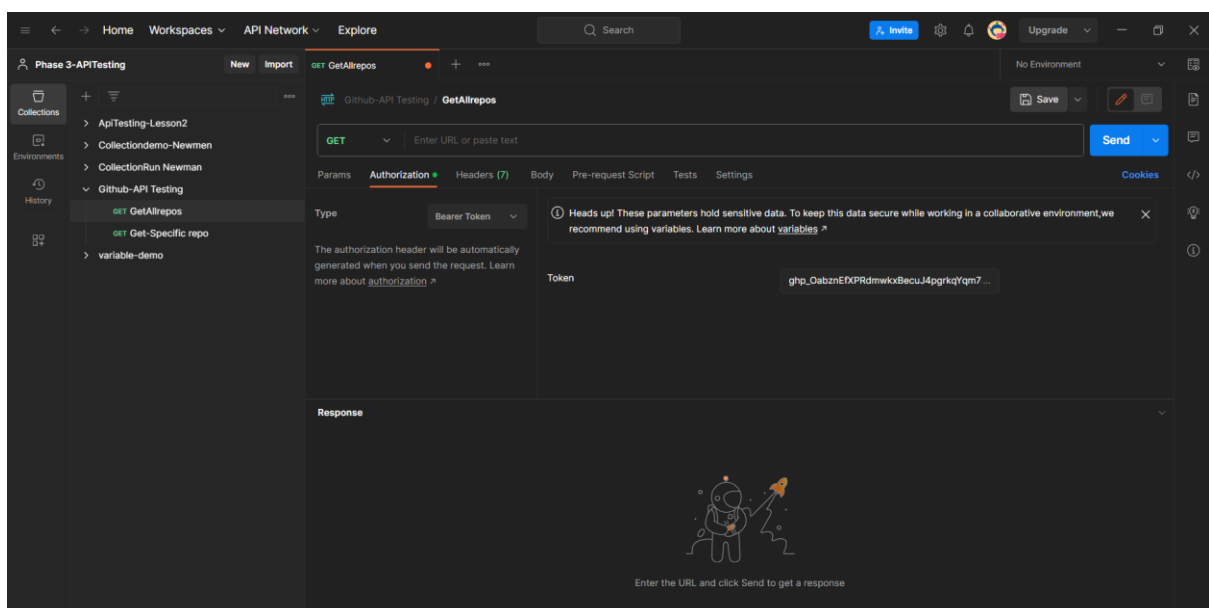

---

(As an example I am getting response for all the repository created by me on github)

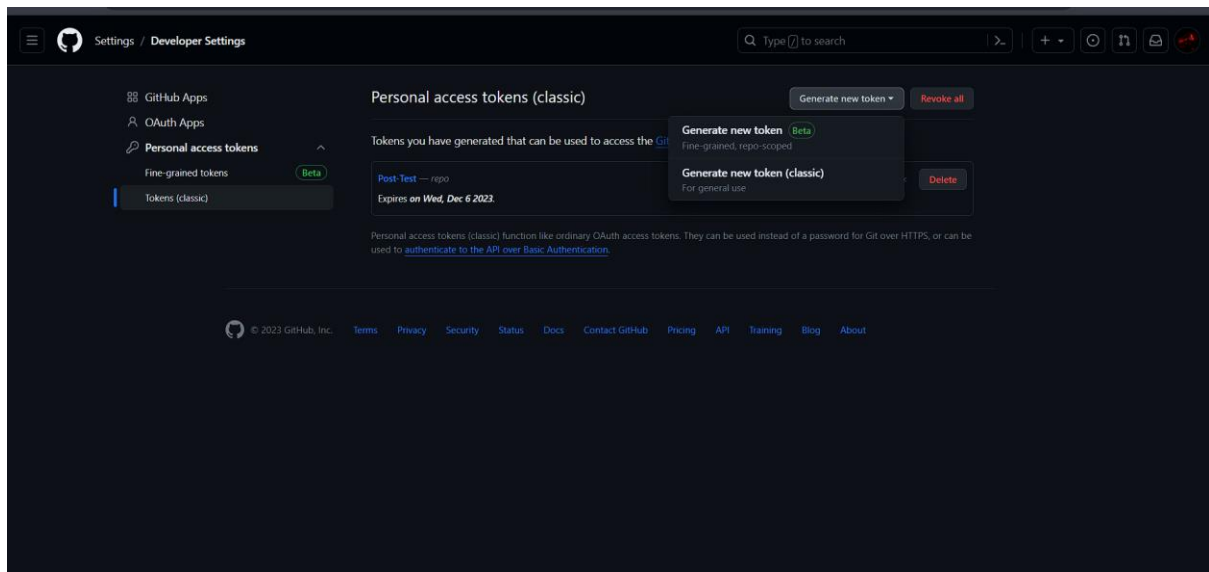

first we will create a black collection as shown below

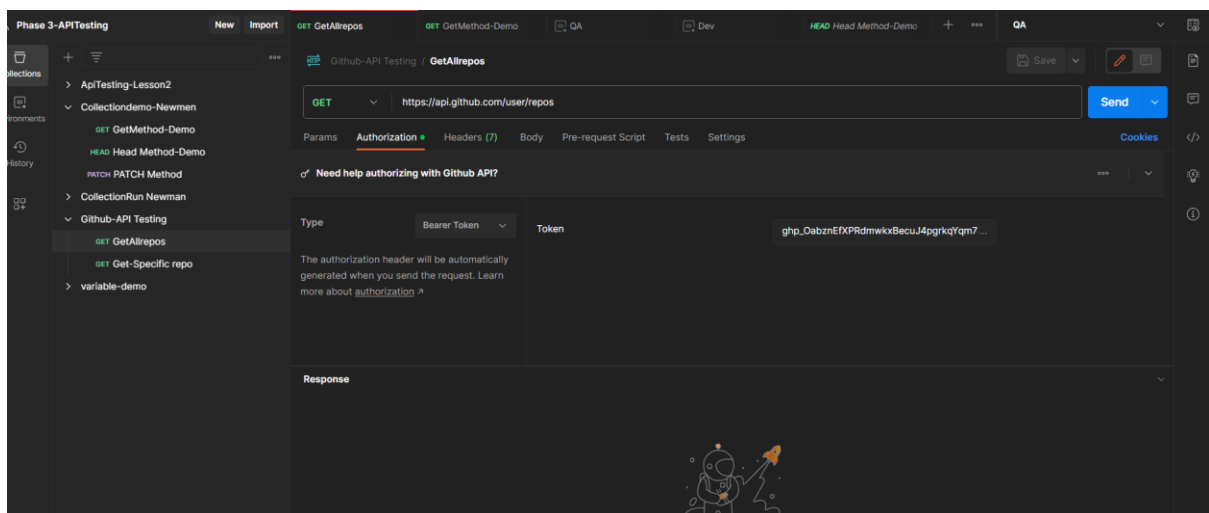

In which we will right click and Add request names as GetAllrepos

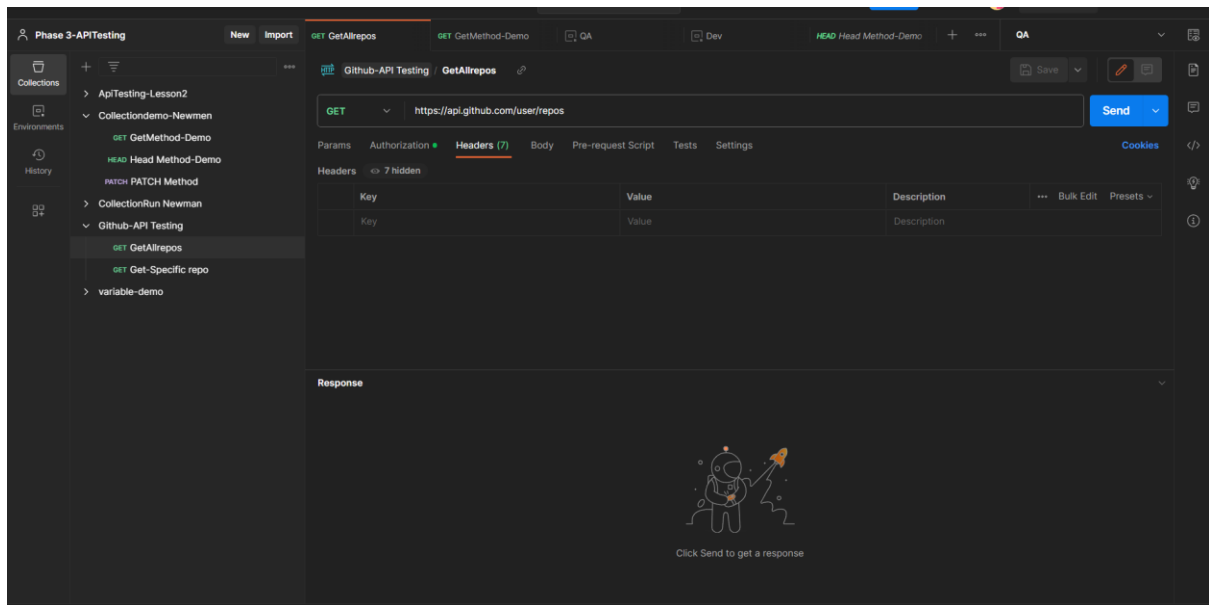

Next we will go to the github and login then go to settings on top right -> Developer settings -> personal access token -> tokens(classics) as shown below

Copy the token and paste on the request Authorization tab, select Bearer Token from the Type dropdown list. In the token field, enter your token value.

Then we will put the URL of the github <https://api.github.com/user/repos>

Now save and click on Send for response, However we will get the response as below
